

**QSORT**

Divide And Conquer

Algorithm of QSORT

C\_Language of QSORT

Running Time of QSORT

# DIVIDE – AND – CONQUER

- An algorithm to make a problem be small ,but similar to original problem.
- **Divide** : Partition the array  $[p \dots r]$  into two subarray  $a[p \dots q]$  and  $a[q+1 \dots r]$  .
- **Conquer** : Sort the two subarray  $A[p \dots q]$  and  $a[q+1 \dots r]$  by recursive calls to qsort .
- **Combine** : When each subarray are sorted in place ,the original array is sorted completely . As the result, it's no need to combine them.

# ALGORITHM OF QSORT

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 2 | 8 | 7 | 1 | 3 | 5 | 6 | 4 |
| 2 | 8 | 7 | 1 | 3 | 5 | 6 | 4 |
| 2 | 8 | 7 | 1 | 3 | 5 | 6 | 4 |
| 2 | 8 | 7 | 1 | 3 | 5 | 6 | 4 |
| 2 | 1 | 7 | 8 | 3 | 5 | 6 | 4 |
| 2 | 1 | 3 | 8 | 7 | 5 | 6 | 4 |
| 2 | 1 | 3 | 8 | 7 | 5 | 6 | 4 |
| 2 | 1 | 3 | 8 | 7 | 5 | 6 | 4 |
| 2 | 1 | 3 | 4 | 7 | 5 | 6 | 8 |

# C\_LANGUAGE OF QSORT[1]

Qsort (A,p,r)

1 if  $p < r$

2     then q     Partition (A,p,r)

3         Qsort (A,p,q-1)

4         Qsort(A,q+1,r)

# C\_LANGUAGE OF QSORT[2]

Partition (A,p,r)

```
1  x    A[r]
2  i    p-1
3  for j p to r-1
4      do if A[j] <= x
5          then i i+1
6              exchange A[i]    A[j]
7  exchange A[i+1]    A[r]
8  return i+1
```

# RUNNING TIME OF QSORT [1]

- The time that qsort cost decided by how we get the partition.

The best partition (balance)

The worst partition (unbalance)

# RUNNING TIME OF QSORT [2]

- How can we get if we always in the best partition.
- $T(n) = 2T(n/2) + O(n)$  (which is approximate to  $n \cdot \log n$ )
- (note : definition of  $T(n)$  and  $O(n)$ )
- Thus the equal balance of two side at every level of the recursion make faster algorithm.
- Note : We say the time qsort cost is  $O(n)$  if

$$\lim_{n \rightarrow \infty} \frac{\text{time}}{n} = \text{const}$$

# RUNNING TIME OF QSORT [3]

Partition (A,p,r)

```
1  x ← A[r]
2  i ← p-1
3  for j ← p to r-1
4      do if A[j] ≤ x
5          then i ← i+1
6              exchange A[i] ← A[j]
7  exchange A[i+1] ← A[r]
8  return i+1
```

# RUNNING TIME OF QSORT [4]

- How can we get if we always in the worse partition.
- $T(n) = T(n-1) + O(n)$  (which is approximate to  $n^2$ )
- What will happen if balance and unbalance cases are mixed ?
- Ex : We always get pivot as the largest or the smallest.

# RUNNING TIME OF QSORT [5]

- In the average case the running time will be much closer to good case. Because when bad and good case are consecutive, bad case will be absorbed into good case.
- $T(n) = T(n-1) + T(0) + O(n) \longrightarrow T(n-1/2 - 1) + T(n-1/2) + O(n)$
- However we can't expect we will not meet the unbalanced case. How to solve this problem?

# RUNNING TIME OF QSORT [6]

- We have know that the average case will close to good case, but how could we make it average ?

Randomized-Partition

```
i ← Random ( p , r )  
exchange A[r] ↔ A[i]  
return Partition ( A , p , r )
```

# Get the best case

- The idea of creating the best case is let qsort can get the midterm number to be pivot. As the result, we can always get balance partition.

pseudo code

Midterm (A, r, p)

1// A is an array which is sorted

2 $A[(p+r)/2 + 1] \leftarrow A[p]$

3Sort  $A[(p+r/2)+1 \dots (p-1)]$

4 $mid = [p + (p+r)/2 + 1] / 2$

5 $A[mid] \longleftrightarrow A[p/2 + 1]$

6Midterm (A, mid, p)

7Partition (A, 0, mid-1)

Partition (A, r, p)

1//A is an array which is sorted

2 $A[p+r / 2] \leftarrow A[p]$

3Sort  $A[(p+r/2)+1 \dots (p-1)]$

4Midterm(A, mid, p)

5Partition(A, r, mid-1)
